(a) From a starting scale to trial caps

ε = 0.5; a = 0.090679

Schematic cap range: logarithmic positions

Search floor:
$\lambda_{min} = \min(a/4, \varepsilon/512) = 0.0009765625$

Seed λ_{min}, a/2, a, 2a, ε; fill logarithmic gaps.
Then refine using measured base + repair bytes.

Search floor ≠ necessary feasibility bound
Anchor a does not guarantee the ACF bound

(b) Repair, store, and decode

x = (0, 1, 2, 1, 0, −1)

b = (−0.5, 0.5, 1.5, 1, 0.5, −1.5)

Constructed base; original-value target t = x

position 5
0.5 → 0

→

position 3
1.5 → 2

→

position 2
0.5 → 1

y = (−0.5, 1, 2, 1, 0, −1.5)
Pass ε = 0.5, ρ = 0.99, τ = 0.1; lags {1, 2}.
Positions 1 and 6 remain inexact.

Example F: mask 0x16 + Float32 values (1, 2, 0)
Stored index order: 2, 3, 5

Format 2 illustration; not claimed to be shortest.

Receiver: decode B → apply F → y; no source needed
